“We shall envision the mind (or brain) as composed of many partially autonomous ”agents” —as a ”Society” of smaller minds. Each sub-society of mind must have its own internal epistemology and phenomenology, with most details private, not only from the central processes, but from one another.”
(Minsky, K-Lines; 1980)

A 4 second recording of the neural activity recording from 30 neurons of the visual cortex of a monkey. Each vertical bar indicates a spike. The human brain can recognize a face within 150ms, which correlates to less than 3mm in this diagram; dramatic changes in firing frequency occur in this time span, neurons have to rely on information carried by solitary spikes.

Action Potential

Neurons fire (spike) to transmit information (mostly)

- 1 Resting membrane potential
- 2 Depolarizing stimulus
- 3 Membrane depolarizes to threshold. Voltage-gated Na^+ channels open and Na^+ enters cell. Voltage-gated K^+ channels begin to open slowly.
- 4 Rapid Na^+ entry depolarizes cell.
- 5 Na^+ channels close and slower K^+ channels open.
- 6 K^+ moves from cell to extracellular fluid.
- 7 K^+ channels remain open and additional K^+ leaves cell, hyperpolarizing it.
- 8 Voltage-gated K^+ channels close, some K^+ enters cell through leak channels.
- 9 Cell returns to resting ion permeability and resting membrane potential.

Black dots represent the EPSP of neurons in the stimulated pathway, white dots represent the EPSP in the unstimulated pathway. Tetanic stimulation was delivered at each arrow.

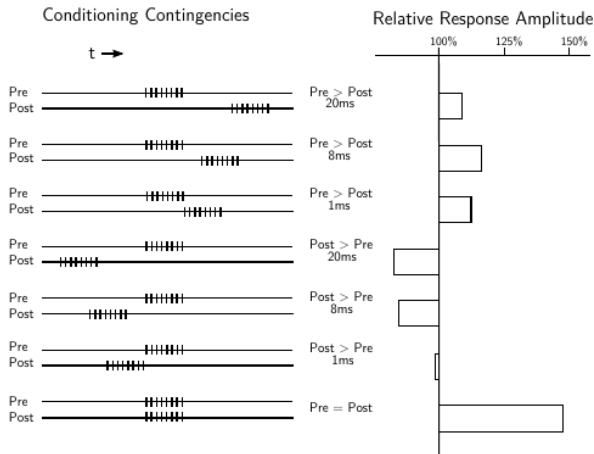

Cartoon depiction of the two classical methods of inducing LTP. Vertical lines do not depict spikes, but pulses applied to the presynaptic cell. + marks show which synapse is potentiated. (A) Homosynaptic (synapse-specific) LTP is induced by high-frequency tetanic stimulus (usually 100Hz for 1 second) of the presynaptic cell. (B) Associative LTP is induced by pairing a tetanic stimulus in one or more presynaptic cells with a low-frequency (usually 5Hz) stimulus in the presynaptic cell whose synapse is to be potentiated. Note that typically the synapses stimulated with the tetanic stimulation will also be potentiated.

Cartoon depiction of the two classical methods of inducing LTD. Vertical lines do not depict spikes, but pulses applied to the presynaptic cell. - marks show which synapse is depressed. (A) Heterosynaptic LTD is induced with tetanic stimulation in some presynaptic cells; those that are not stimulated may become depressed. Note that the stimulated cells often have their synapses potentiated. (B) Homosynaptic LTD is induced with long period of low-frequency stimulation (typically 1 Hz for 10 minutes) of the presynaptic cell.

Evidence that the temporal order of pre- and postsynaptic stimulation affects the induction of LTP/LTD. (Left) The stimulation protocol. Each vertical line represents a pulse of current. (Right) The ratio of the amplitude of the EPSP before the stimulation protocol and 20 minutes after the stimulation protocol. Note that depression happens when postsynaptic neurons are stimulated before presynaptic neurons, potentiation when presynaptic neurons are stimulated before postsynaptic neurons, and strong potentiation occurs when they are simultaneously stimulated.

Spike-timing dependent plasticity

The STDP curve. Each dot represents the relative change in synaptic strength after 60 pre-post or post-pre spike pairings.

Feed-forward networks with omniscient top-down knowledge are good at static feature extractions (e.g., AlphaGo)

From-scratch backprop beats you at digit class:

With no fancy libraries, from scratch, and this is the entire source (minus a 3-4 line main)

```

def sigmoid(x):
    return 1.0/(1.0 + np.exp(-x))

def sigmoid_prime(x):
    return sigmoid(x)*(1.0 - sigmoid(x))

class NN:
    def __init__(self, nI=3, nH=4, nO=1):
        self.syn1 = 2 * np.random.random((nH, nO)) - 1

    def runNN(self, X):
        self.l0 = X
        self.l1 = sigmoid(np.dot(self.l0, self.syn0))
        self.l2 = sigmoid(np.dot(self.l1, self.syn1))
        return self.l2

    def backPropagate(self, y, N):
        l2_error = y - self.l2
        l2_delta = l2_error * sigmoid_prime(self.l2)
        l1_error = l2_delta.dot(self.syn1.T)
        l1_delta = l1_error * sigmoid_prime(self.l1)
        self.syn1 += (self.l1.T.dot(l2_delta)) * N
        self.syn0 += (self.l0.T.dot(l1_delta)) * N

    def train(self, X, y, max_iterations=10000, N=0.8):
        for roundNum in range(max_iterations):
            self.runNN(X)
            self.backPropagate(y, N)

    def test(self, X, y):
        final_prediction = self.runNN(X)
        return np.mean((final_prediction - y)**2)
  
```

each pre-synaptic spike generates an EPSP (red curves) or IPSP in case of negative weight ; they are all added (blue line) ;

when $u_j(t)$ reaches the threshold V the post-synaptic neuron N_j emits a spike, in its turn.

Schematic drawing of the integrate-and-fire neuron. On the left side, the low-pass filter that transforms a spike to a current pulse $I(t)$ that charges the capacitor. On the right, the schematic version of the soma, which generates a spike when voltage u over the capacitor crosses threshold.

u being the membrane potential,

$$C \frac{du}{dt} = -\frac{1}{R}(u(t) - u_{rest}) + I(t)$$

spike firing time $t^{(f)}$ is defined by

$$u(t^{(f)}) = \vartheta \quad \text{with} \quad u'(t^{(f)}) > 0$$

Leaky Integrate and fire (LIF)

Circuit diagram that corresponds to the leaky integrate-and-fire (LIF) neuron

- $J(t)$ is weighted sum of inputs
- R is resistance
- C is membrane capacitance
- $V(t)$ is voltage at time t
- And the model is: $\frac{dV}{dt} = -\frac{1}{RC}(V(t) - J(t)R)$

Membrane voltage of a LIF neuron with constant input J_i .

Leaky Integrate and fire (LIF)

Time course of the membrane potential $u(t)$ of a leaky-integrate-and-fire neuron LIF (panel C) driven by the external input current $i_o(t)$ (shown in panel A) or by the synaptic current $i_j(t)$ evoked by the sample presynaptic spike train (panel B). Initially, the state $u(t)$ of the LIF neuron is at the resting value u_{res} . The currents $i_o(t)$ and $i_j(t)$ increase the membrane potential towards the firing threshold θ . Whenever the threshold is crossed the neuron emits a spike and the membrane voltage $u(t)$ is reset to a new value - here assumed u_{res} . The firing times of the LIF neuron are shown as vertical bars in panel D.

$$u_i(t) = \eta(t - \hat{t}_i) + \sum_j \sum_f \epsilon_{ij}(t - t_j^{(f)}) + u_{rest}$$

Potential:

$$\eta(t - t_i^{(f)})$$

spike (stereotyped):

EPSP:

$$u_i(t) = \vartheta \text{ and } \frac{d}{dt} u_i(t) > 0 \implies t = t_1^{(f)}$$

spike-condition:

Dynamics of the theta model on the unit circle. Blue denotes a stable fixed point; Green denotes an unstable fixed point. By varying the input parameter, the two equilibria collide and form a stable limit cycle; Gray arrows indicate that the points are attracting in \mathbb{R}^2 ; Black arrows indicate the direction of movement along the unit circle

The phase-trajectory in a Theta-neuron evolves according to:

$$\frac{d\theta}{dt} = (1 - \cos(\theta)) + \alpha I(t)(1 + \cos(\theta)),$$

where theta is the neuron phase, alpha is a scaling constant, and $I(t)$ is the input current. The main advantage of the Theta-neuron model is that neuronal spiking is described in a continuous manner, allowing for more advanced gradient approaches

Diversity of neuron types

“What magical trick makes us intelligent? The trick is that there is no trick. The power of intelligence stems from our vast diversity (and size), not from any single, perfect principle.” (Marvin Minsky, Society of Mind; 1987)

Comparison of the neuro-computational properties of spiking and bursting models; "number of FLOPS" is an approximate number of floating point operations (addition, multiplication, etc.) needed to simulate the model during a 1 ms time span. Each empty square indicates the property that the model should exhibit in principle (in theory) if the parameters are chosen appropriately, but the author failed to find the parameters within a reasonable period of time.

Coding by relative delay. The neurons in figure emit spikes at different moments (f) in time t_j . The most strongly activated neuron fires first (i.e., second from left). Its spike travels a considerable distance along the axon, until last neuron fires (i.e., the fourth from left). The latencies x_j are computed with respect to a reference time T

- The first was Hebbian: $\Delta\omega_{ij} = \kappa a_i a_j$ where:
 - ω_{ij} is the synaptic strength of the synapse between the axon of the presynaptic neuron i and the dendrite of the postsynaptic neuron j .
 - $\Delta\omega_{ij}$ is change in synaptic strength
 - κ is the learning rate
 - a_i indexes the presynaptic neuron
 - a_j indexes the postsynaptic neuron
 - “Activity” can be interpreted many different ways. The most common measure of activity is the firing rate of a neuron. However, membrane voltage, spike times, the amount of current flowing into the cell, filtered spike trains, and other measures can be interpreted as activity.

Construct a network with arbitrary connection weights, ω . Given

- $S(t_j^d)$, the desired spike train of output neuron j , and
- $S(t_i)$, the spike train of an input neuron i ,

modify ω such that

$$D(S(t_i), S(t_j))$$

is minimized, where $D(S_1, S_2)$ is a measure of the dissimilarity between two spike trains [47, 214].

- SpikeProp, operates much like traditional backpropagation in that it calculates the global error – the time difference between the spike train created by the network and the desired spike train – and assigns local error for each node, which is used to modify connection weights proportionally to the node’s activity. Like backpropagation, however, the local error for each node depends on the connection weights of downstream neurons, making this algorithm biologically implausible. It also requires the network be feed-forward

The unsupervised spike-time learning problem

Given input \mathbf{X} and cost function $C(\mathbf{x}, \mathbf{y})$, generate output \mathbf{Y} and minimize $C(\mathbf{x}, \mathbf{y})$.

- Various rules:
 - Artola, Brocher, Singer (ABS) - rate based
 - Bienenstock, Cooper, Munro (BCM) - rate based
 - Spike-timing dependent plasticity rules - timing based
 - $\Delta\omega_{ij}(t^{pre}) = A^- \exp\left(\frac{t^{post_l} - t^{pre}}{\tau^-}\right)$
 - $\Delta\omega_{ij}(t^{post}) = A^+ \exp\left(\frac{t^{post_l} - t^{post}}{\tau^+}\right)$
 - t^{pre} is time of a presynaptic spike
 - t^{pre_l} is time of the last presynaptic spike
 - t^{post} and t^{post_l} for postsynaptic
 - A^- is a negative constant representing the max amp post-pre depression
 - τ^- is time-constant controlling exponential decay
 - A^+ and τ^+ define positive pre-post part of the curve

Encoding with overlapping Gaussian receptive fields. An input value a is translated into firing times for the input-neurons encoding this input-variable. The highest stimulated neuron (5), fires at a time close to 0, whereas less stimulated neurons, as for instance neuron 7, fire at increasingly later times.

Three clusters (upper left and upper right) of different scale with noise (crosses). (b,c) Insets: actual classification. Respective classes are marked with diamonds, squares, and circles. Noise outside the boxes or points marked by x's did not elicit a spike and were thus not attributed to a class. Side panels: graded receptive fields used.

Reservoir (supervised or reinforcement)

- Reservoir performance is improved with unsupervised STDP in reservoir.

Given some information about a Markov Decision Process,

$$MDP = (\mathcal{S}, \mathcal{A}_s, \mathcal{P}_a(s, s'), \mathcal{R}_a(s, s')),$$

find a policy $\pi(s) = a$ such that following that policy maximizes

$$R = \sum_{t=0}^{\infty} \gamma^t r_{t+1}.$$

Changes of the synaptic weight $w(t)$ are proportional to the product of the STDP eligibility trace $c(t)$ with the reward signal $d(t)$. Contribution of a pre-before-post spike pair and a post-before-pre spike pair to the eligibility trace $c(t)$ is illustrated at the top of the figure

Eligibility trace modulates effects that would occur with normal STDP (see, for example, the dip after a post-pre pairing). The delivered reward allows the plasticity to occur, raising the synaptic strength

Various ways to make a network do R-STDP:

- Neuron-level (each neuron integrates reinforcement, like dopamine) with various flavors within this set
- Actor-Critic: Population level (e.g., neuron compiler)

Variants on STDP:

- Triplets, etc
