Balance

- Binary search trees keep their keys in sorted order.
- BST is a tree whose internal nodes each store a comparable or key (and optionally an associated value), and each key must be greater than any key stored in its left sub-tree, and less than (or sometimes equal to) any key stored in its right sub-tree.
- For every node,  $X$ , in the tree, the values of all the keys in its left subtree are smaller than the key in  $X$ , and the values of all the keys in its right subtree are larger than the key in  $X$ .
- Fast lookup, addition and removal of keys ( $\log_2 n$ )
- On average, each lookup, insertion or deletion takes time proportional to the logarithm of the number of items stored in the tree. This is the key advantage over a continuously sorted list.
