Sorting arrays

Random stuff

- An array is a series of elements of the same type placed in contiguous memory locations that can be individually referenced by adding an index to a unique identifier.
- That means that, for example, five values of type `int` can be declared as an array without having to declare 5 different variables (each with its own identifier).
- Instead, using an array, the five `int` values are stored in contiguous memory locations, and all five can be accessed using the same identifier, with the proper index.
- For example, an array containing 5 integer values of type `int` called `foo` could be represented as:

```
int foo [5];
```

Arrays as parameters to functions

Multidimensional arrays to functions

Sorting arrays

Random stuff

```
int foo [5] = { 16, 2, 77, 40, 12071 };
```

The number of values between braces shall not be greater than the number of elements in the array. For example, in the example above, `foo` was declared having 5 elements (as specified by the number enclosed in square brackets, `[]`), and the braces contained exactly 5 values, one for each element.

If declared with less, the remaining elements are set to their default values (which for fundamental types, means they are filled with zeroes). For example:

```
int bar [5] = { 10, 20, 30 };
```

The initializer can even have no values, just the braces:

```
int baz [5] = { };
```

For example, the following statement stores the value 75 in the third element of foo:

```
foo [2] = 75;
```

```
x = foo [2];
```

and, for example, the above copies the value of the third element of foo to a variable called x:

It is possible to declare an array and initialize it with a sequence of elements, but no size specified:

```
double collection [] = { 1.0, 3.5, 0.5, 7.2 };
```

Two-dimensional arrays with initializer lists can omit (**only**) the leftmost length specification:

```
int array[][5] =
{
{ 1, 2, 3, 4, 5 },
{ 6, 7, 8, 9, 10 },
{ 11, 12, 13, 14, 15 }
};
```

Array basics

Declaration

Assignment and access

Arrays as parameters to functions

Multidimensional arrays to functions

Sorting arrays

Random stuff

NOT OK. The compiler can do the math to figure out what the array length is. However, the following is not allowed:

```

int array [][] =
{
{ 1, 2, 3, 4 },
{ 5, 6, 7, 8 }
};
  
```

- In C++, we don't want to pass the entire block of memory represented by an array to a function directly as an argument.
- But what can be passed instead is its address.
- In practice, this has almost the same effect, and it is a much faster and more efficient operation.

```
void procedure(int arg [])
```

```
int main()
{
  int myarray [40];
  procedure(myarray);

```

...

Notice that the first brackets `[]` are left empty, while the following ones specify sizes for their respective dimensions. Including the other dimensions is necessary in order for the compiler to be able to determine the depth of each additional dimension.

```
void procedure (int myarray [][][3][4]);
```
