[Definitions](#)[Template parameters](#)[Template specialization](#)

- Templates are the foundation of generic programming, which involves writing code in a way that is independent of any particular type.
- Generic programming is a style of computer programming in which algorithms are written in terms of types to-be-specified-later that are then instantiated when needed for specific types provided as parameters.
- Templates are a feature of the C++ programming language that allows functions and classes to operate with generic types. This allows a function or class to work on many different data types without being rewritten for each one.

The general form of a template function definition

Template specialization

General syntax for a Function (review)

```
template <typename type>
ret-type func-name(parameter list)
{
    // body of function
}
```

General syntax for a class

```
template <typename type>
class class-name
{
    //class contents
    .
    .
}
```

Template
specialization

template < parameter-list > declaration

Each parameter in parameter-list may be:

- a non-type template parameter;
 - A value that has an integral type or enumeration
 - A pointer or reference to a class object
 - A pointer or reference to a function
 - A pointer or reference to a class member function
- a type template parameter;
- a template template parameter.

Template specialization

- specialization is a definition for a particular type or types that is to be used instead of the general template.
Sometimes you might need or want to modify a template to behave differently when instantiated for a particular type; in that case, you can create an explicit specialization.
- Can be either full or partial (in regard to number of parameters being specialized)
